Step 1. Sign in

> KDL OS must already be installed and running. If not, follow the **Installation** guide first (Admin > Documents > Installation).

Open **http://localhost/login**. Email `admin@kdl.com`, password `kdl-dev-seed-password`. KDL OS asks you to choose a new password on first sign-in.

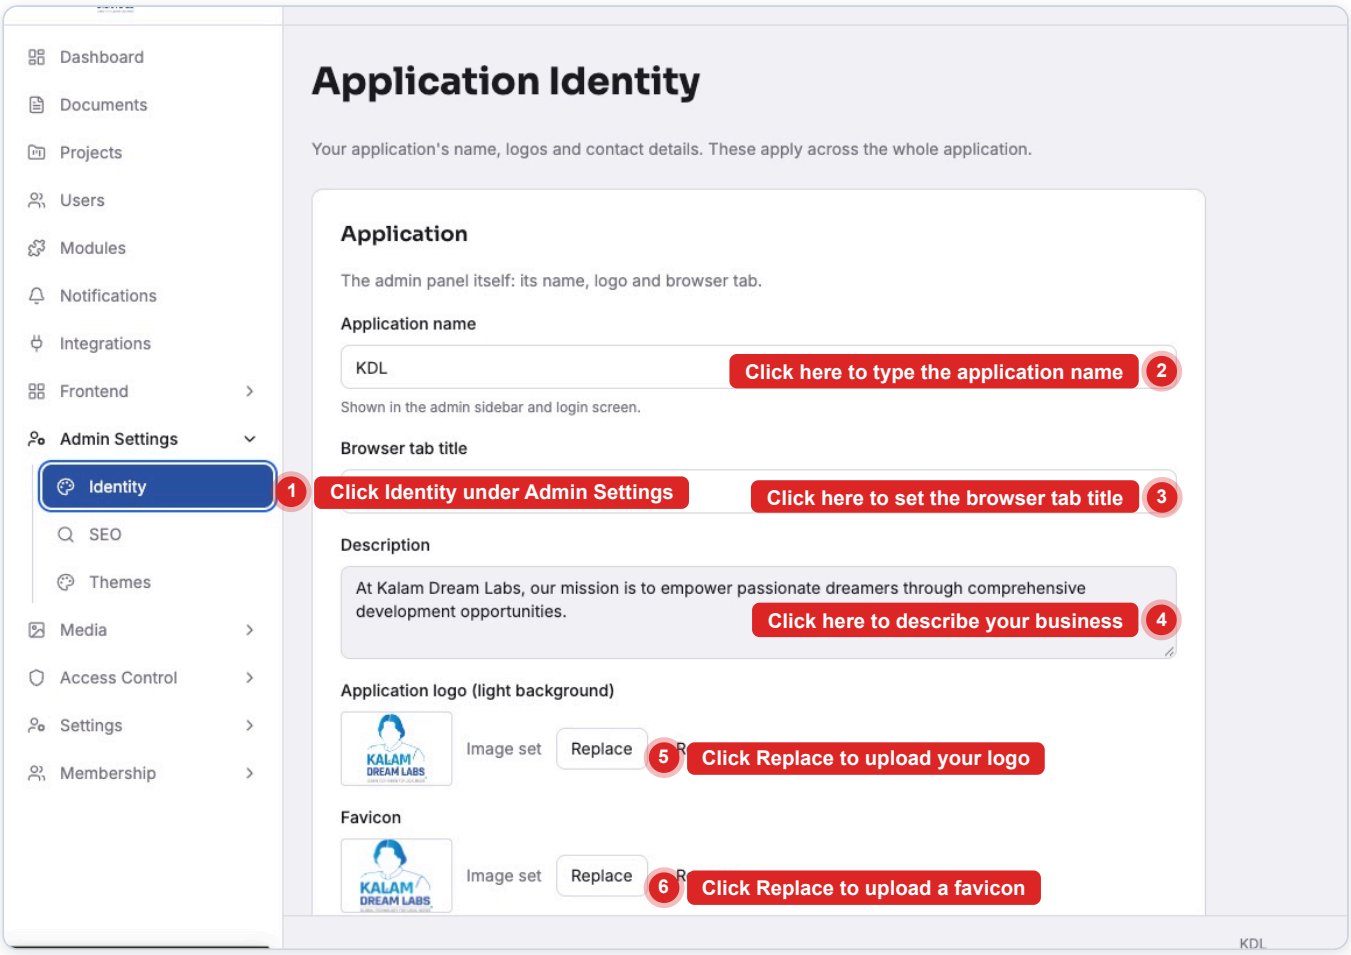

The sign-in screen

> Forgot the password or locked out? `docker compose exec backend node scripts/reset-admin-password.js --email admin@kdl.com --password 'Admin@123'` (at least 8 characters), then sign in with it. 429 or "Account locked" while testing: wait a minute or `docker compose restart backend`.

Step 2. Open Application Identity

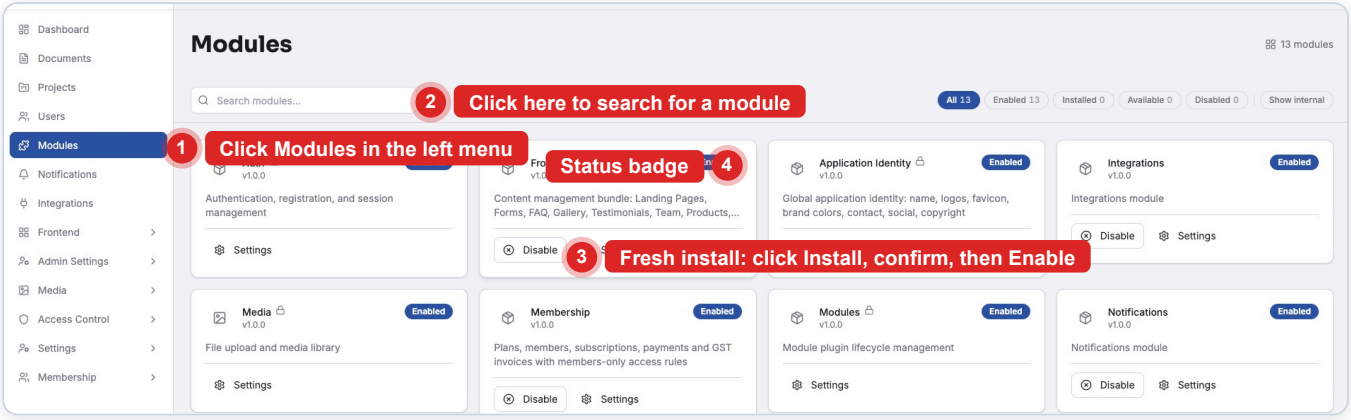

After you sign in, open **Admin Settings > Identity** in the left menu. This is where the application name, logo and favicon are set.

Admin Settings > Identity

Step 3. Open Modules, install and enable Frontend

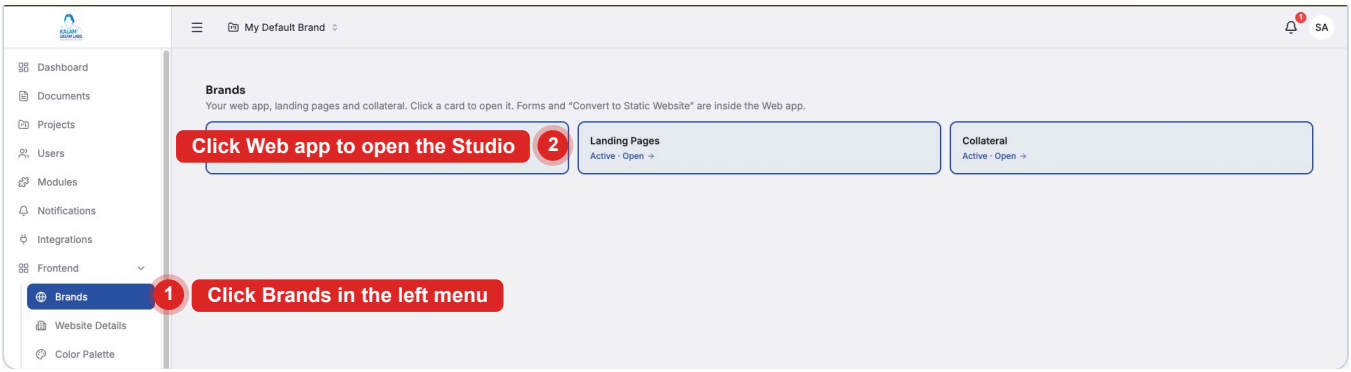

Click **Modules** in the left menu. Find the **Frontend** card (use the search box if you need to). On a fresh install the card shows **Install**: click it and confirm, then click **Enable** and confirm. The badge changes to **Enabled**.

Modules: the Frontend card

Step 4. Open the Studio

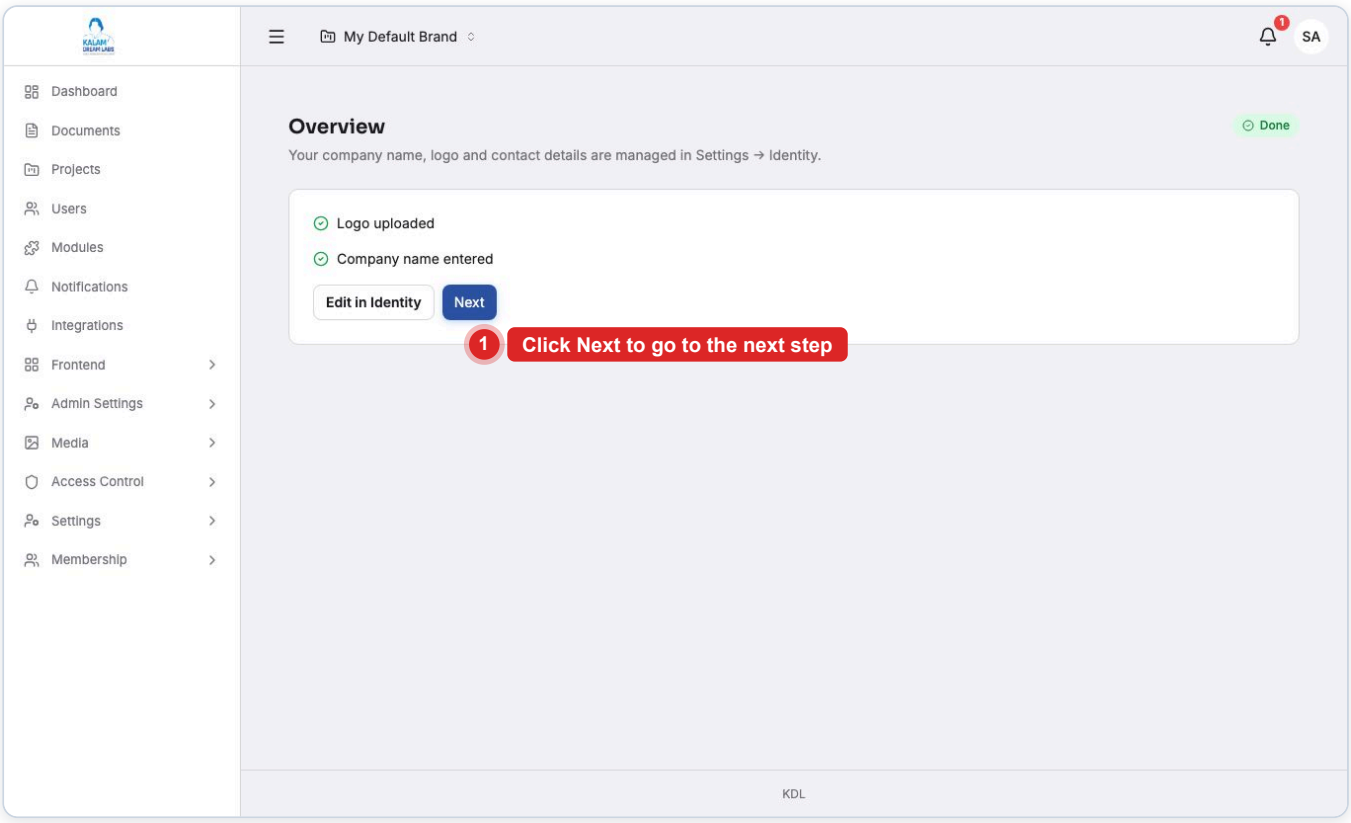

Click **Frontend > Brands** in the left menu, then click the **Web app** card. This opens the Studio for your website. The first time, click **Start Studio run**. Tabs along the top: Overview, Color Palette and Website.

Brands: open the Web app

Step 5. Studio Overview: logo and company details

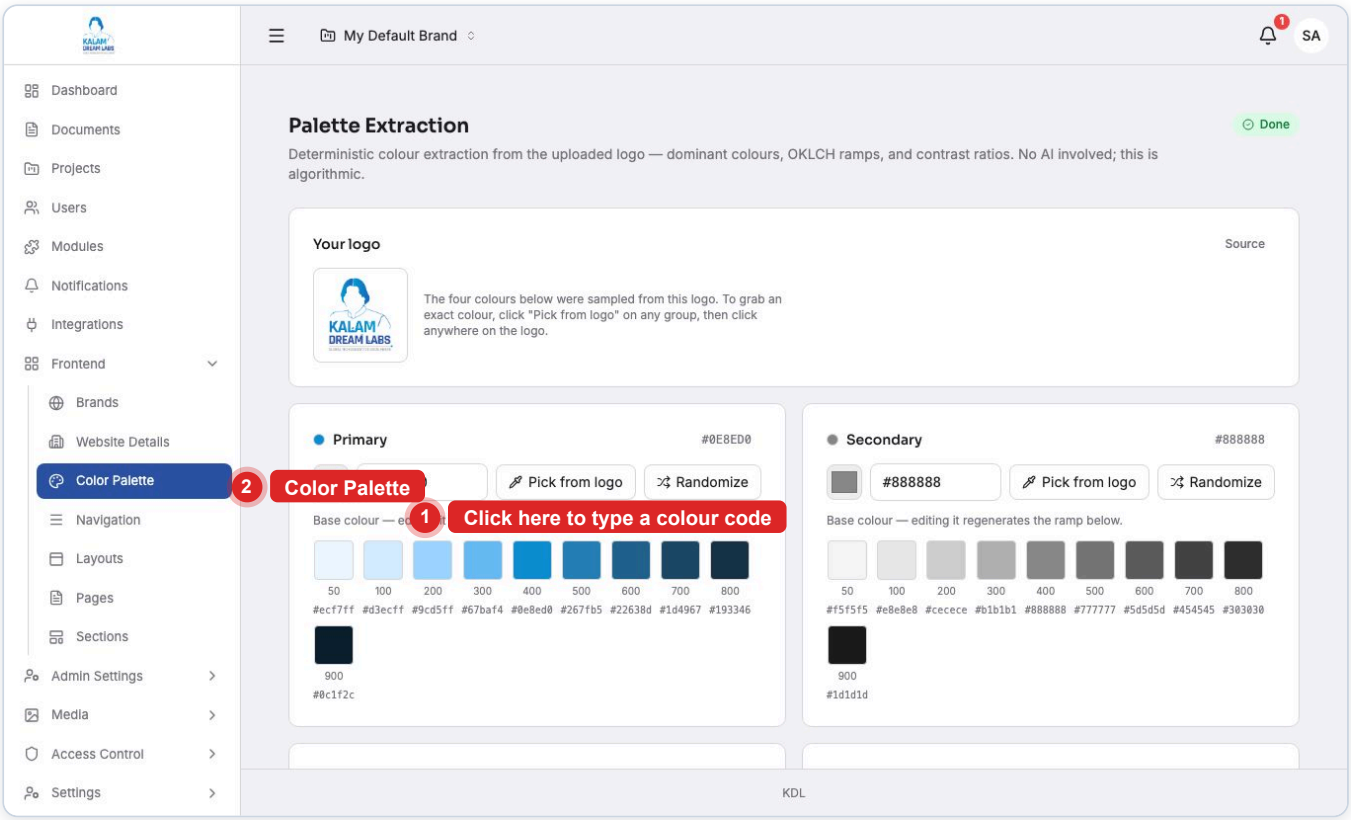

Upload your logo (svg, png, jpeg or webp), check the company and contact details, then click **Next**. Use **Edit in Identity** to change the details. The logo also becomes the admin logo.

Studio: Overview

Step 6. Color Palette

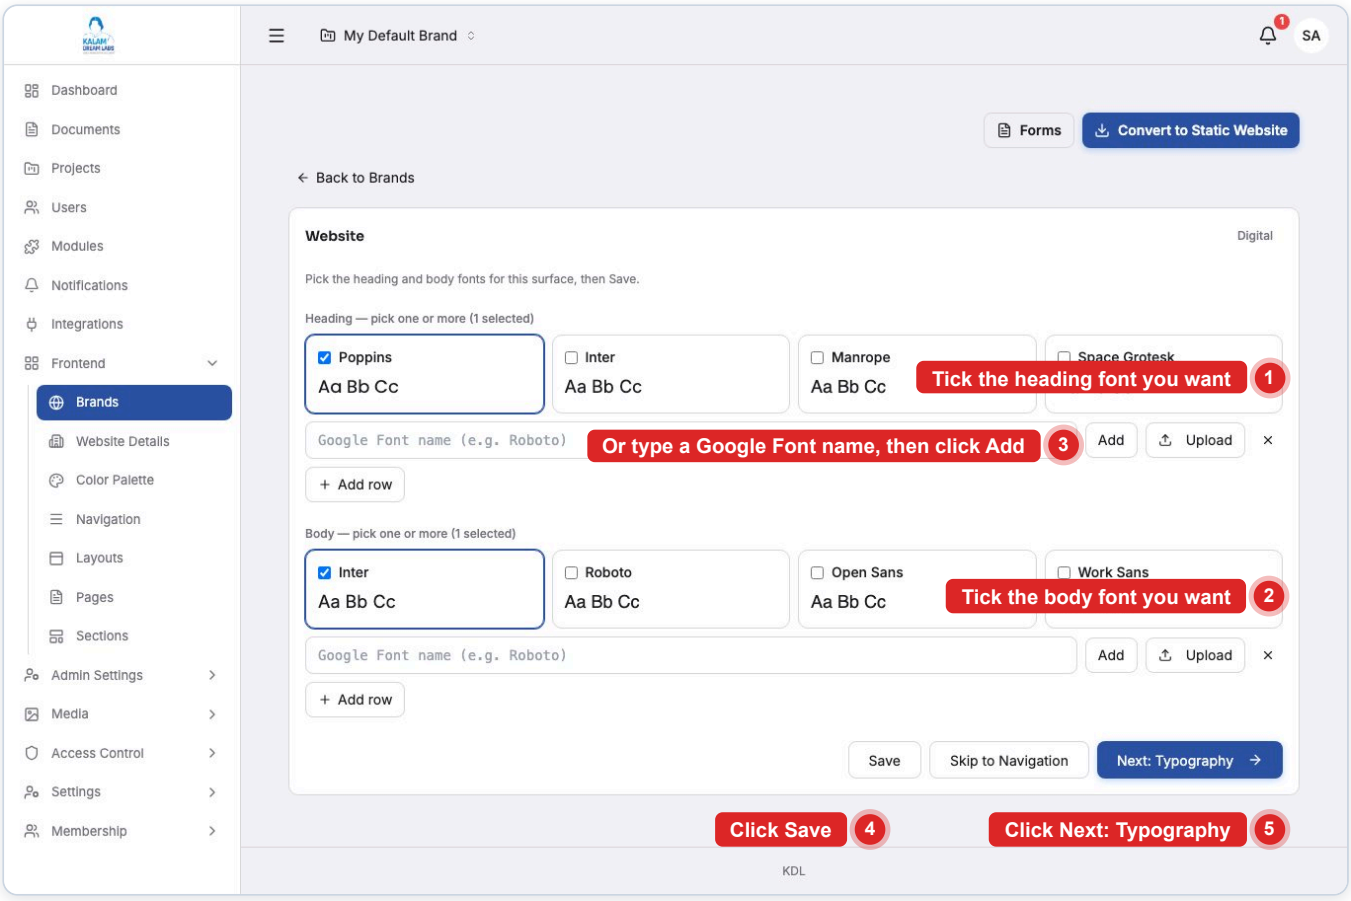

Four brand colours are taken from your logo: Primary, Secondary, Tertiary and Quaternary. Keep them, or click a colour box and type a new code, click **Pick from logo** or **Randomize**. Then click **Submit palette**. The colours become the website's design tokens.

Studio: Color Palette

Step 7. Typography: choose the fonts

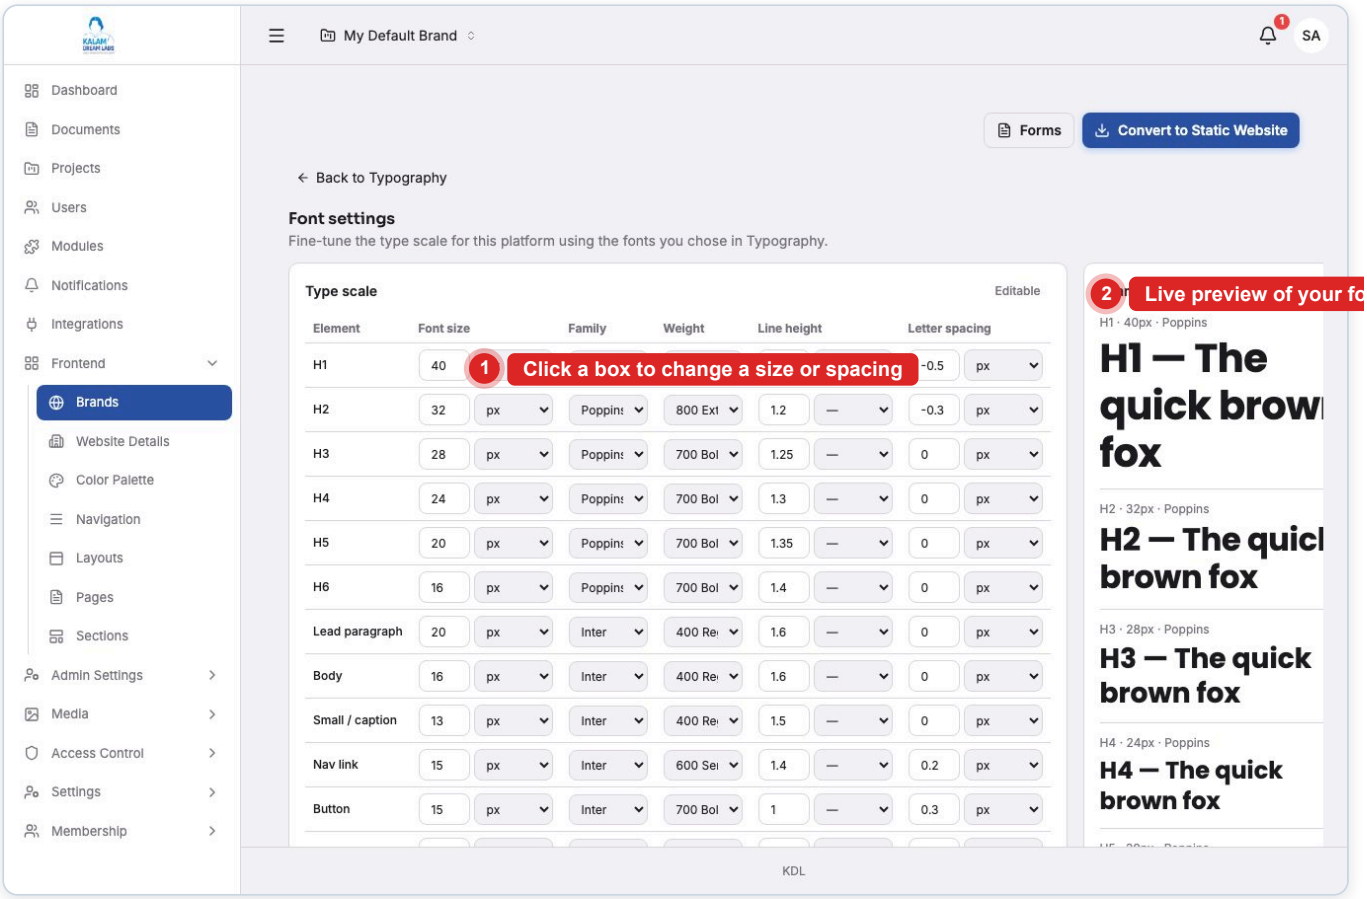

The Website stage opens on **Typography**. Under **Heading** tick the font for titles, and under **Body** tick the font for normal text. To use another font, type its Google Font name (for example Roboto) and click **Add**, or click **Upload** to add your own font file. Click **Save**, then click **Next: Typography** to continue.

Website stage: Typography

Step 8. Font settings

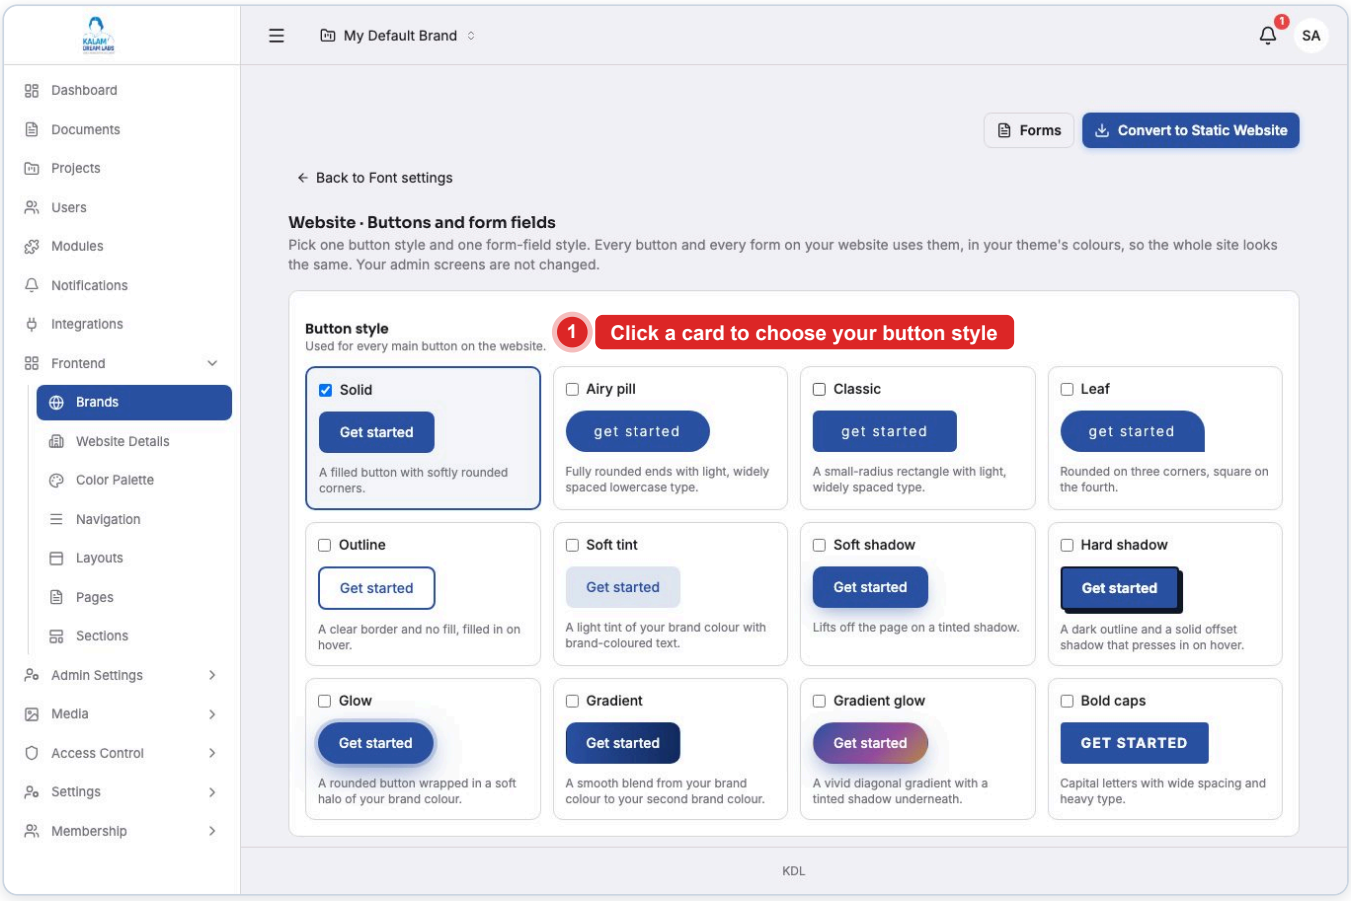

Fine-tune the type scale: for each element (H1 to H6, Lead paragraph, Body, Small, Nav link, Button) change the font size, family, weight, line height and letter spacing. The **Examples** panel on the right shows the result live. The defaults are a good start. Scroll down and click **Next: Buttons and form fields**.

Website stage: Font settings

Step 9. Buttons and form fields

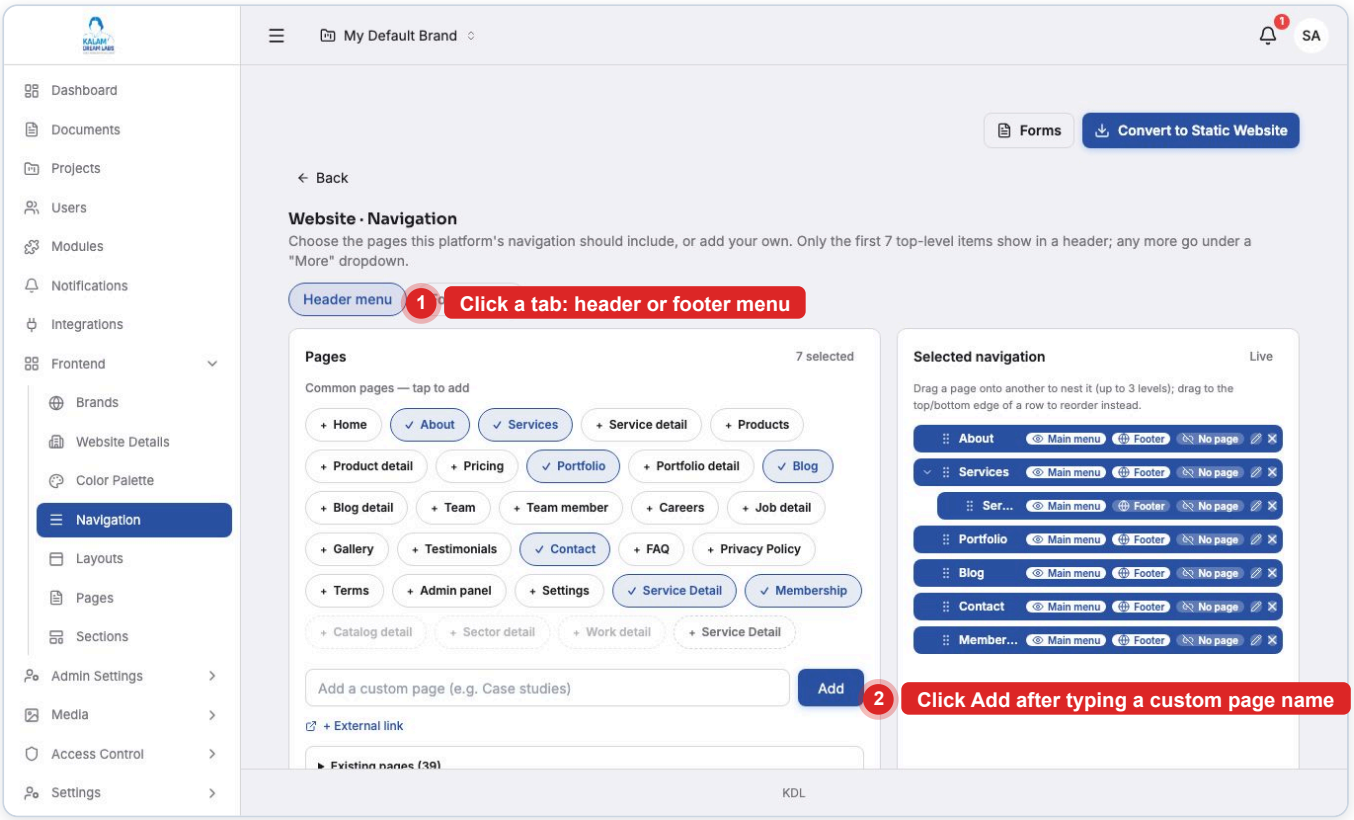

Click one card under **Button style** (Solid, Airy pill, Classic, Leaf, Outline, Soft tint and more), then scroll down and click one card under **Form field style**. Every button and every form on your website uses them, in your theme's colours. The admin screens are not changed. Click **Next** to continue to Navigation.

Website stage: Button style

Step 10. Choose the menu pages

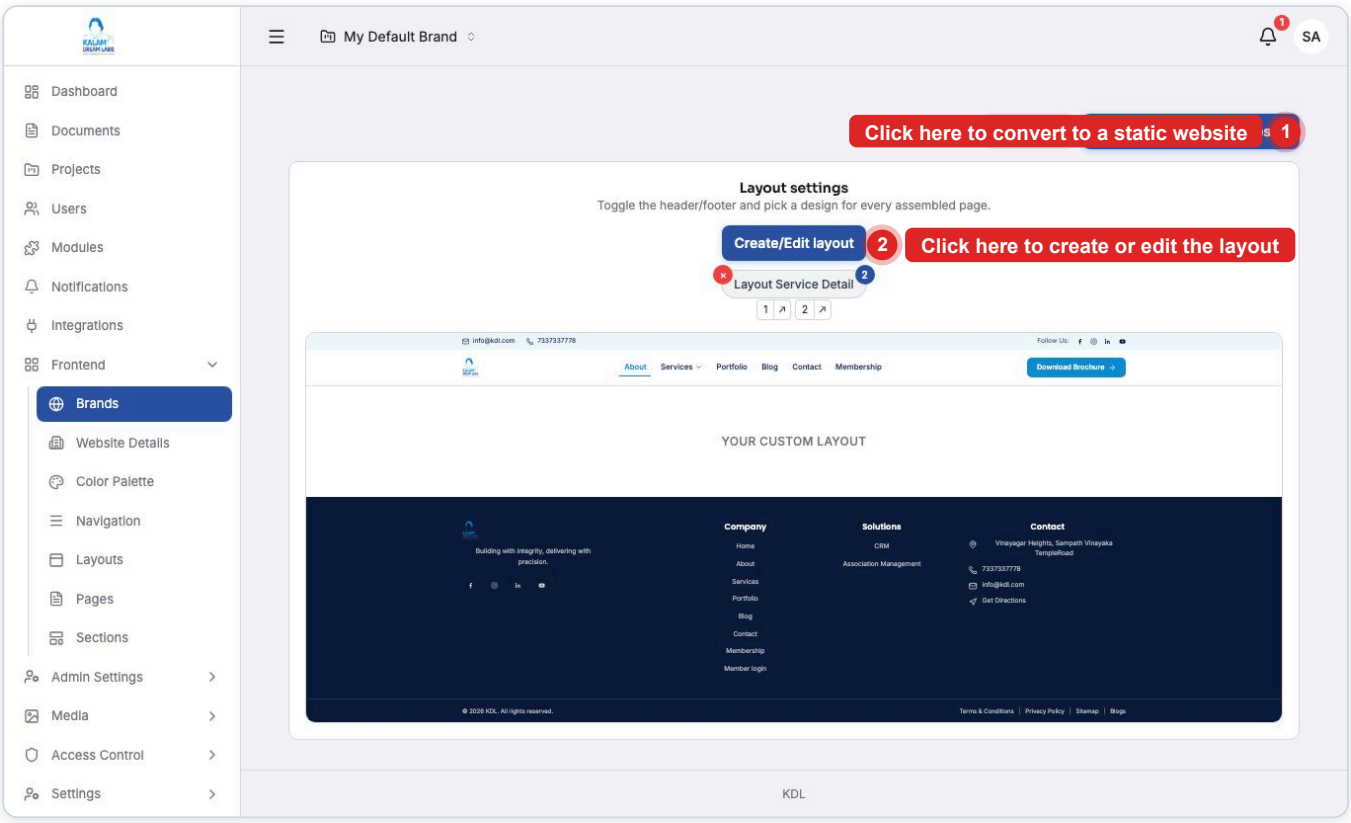

Open **Frontend > Navigation**. Click the page names you want in the menu (About, Services, Portfolio, Blog, Contact and so on), or type a custom page and click **Add**. Use the **Header menu** and **Footer menu** tabs. One page is created for every menu item, plus Home.

Frontend > Navigation

Step 11. Website stage: layout

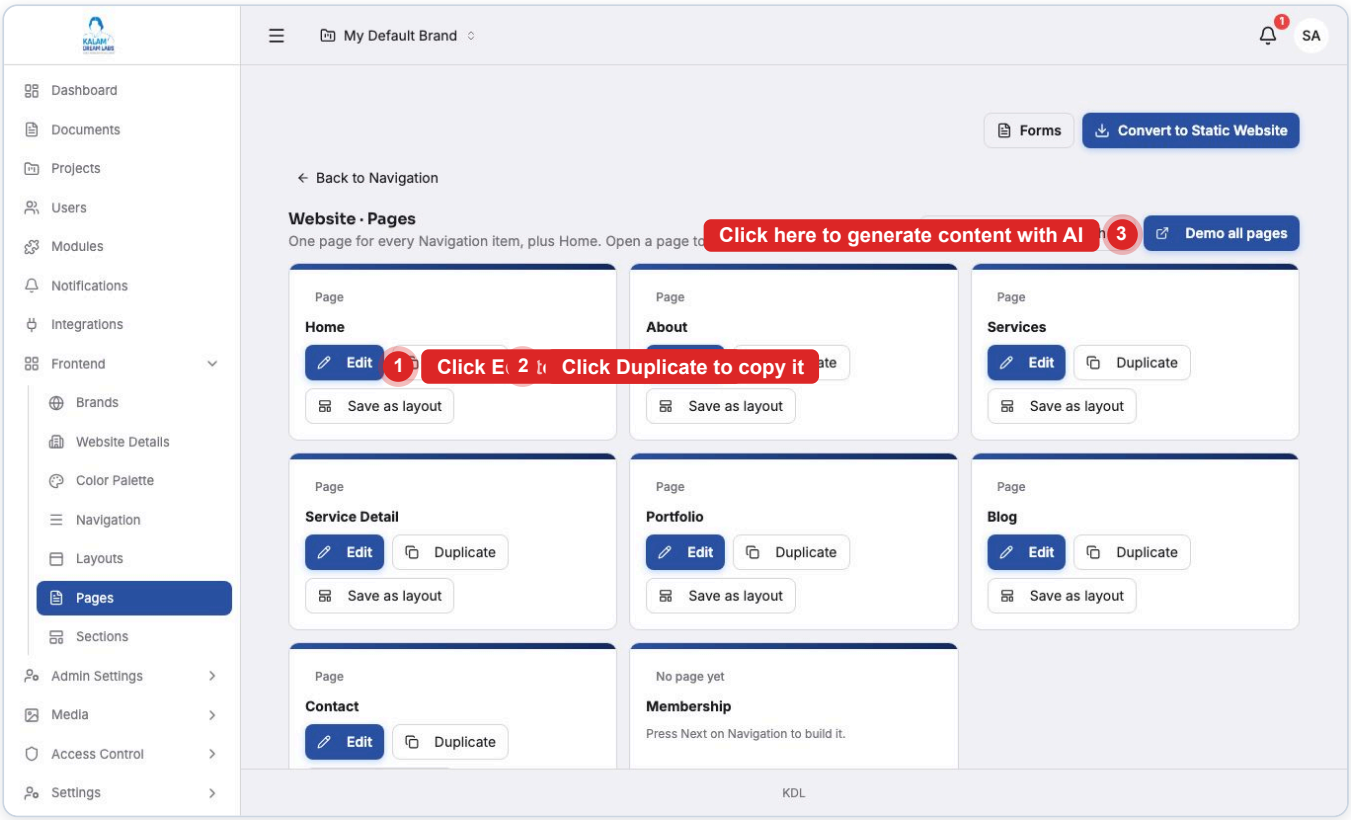

Set typography and fonts. Click **Create/Edit layout** to choose the Top header, Header and Footer. The header and footer of **Home** are shared by every public page.

Studio: Website stage

Step 12. Edit and publish the pages

Open **Frontend > Pages**. Click **Edit** on a page to change its text, images and links in the section builder, then **Save** and **Publish**. Publish stops real problems (an empty page, a missing title, a broken link) and only suggests the rest. Click **Duplicate** to copy a page. **Frontend > Sections** holds reusable sections.

Frontend > Pages

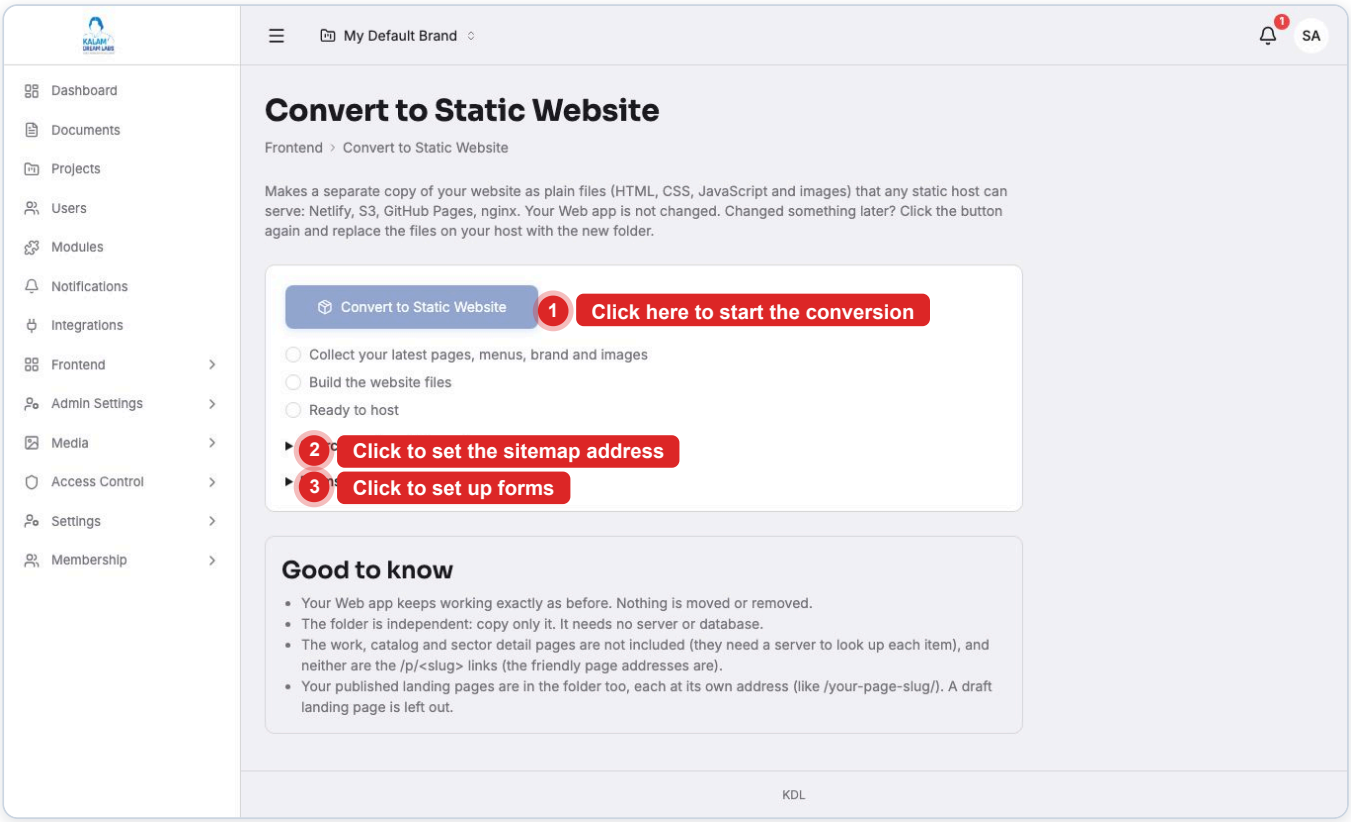

Step 13. Check the live website

Open http://localhost in a private window, signed out. Check that the header and footer match Home on every page and that every menu link opens a page. Pages are public at `/` and at `/p/<slug>`.

Step 14. Convert to a static website

Static files (HTML, CSS and images) can be hosted anywhere with no server. Publish your pages first, then click **Convert to Static Website** (the button at the top of the Studio, or http://localhost:3001/admin/static-website).

Optional: type your **Website address** (for example https://www.example.com) to add a sitemap. Type your **Web app address** (https only) if forms must keep working; if you leave it empty, forms show your contact email and phone. Click **Convert to Static Website** and wait a few minutes until the card says it is ready.

Frontend > Convert to Static Website

Step 15. Download the files and host them on GitHub

Click **Download as .zip** on the same page and unzip it. The files inside, with `index.html` at the top, are your finished website.

1. On GitHub create a new empty repository, for example `my-website`.
2. Put the files in a new folder, open a terminal in it, and run (use your own username and repository name):

```
TERMINAL
git init
git add .
git commit -m "Website"
git branch -M main
git remote add origin https://github.com/YOUR-USERNAME/my-website.git
git push -u origin main
```

3. On GitHub open **Settings > Pages**, choose **Deploy from a branch**, pick **main** and the **/ (root)** folder, then **Save**.
4. After a minute your website is live at `https://YOUR-USERNAME.github.io/my-website/`.

Notes: Changing things later

This is not a step. Use it when something changes.

- **Text, images, links:** Frontend > Pages, Edit, Save, Publish. No re-run is needed.
- **Menus:** Frontend > Navigation.
- **Header, top bar or footer:** Studio > Layouts > Create/Edit layout.
- **Colours or fonts:** Studio > Color Palette, Submit palette.
- After any change: publish, then click **Convert to Static Website** again, replace the files in your GitHub folder, then `git add .`, `git commit -m "Update"` and `git push`. The static copy never updates itself.
